Fibred Product of Commutative Algebras: Generators and Relations

Timofeeva N. V.

Received April 15, 2016

Abstract. The method of direct computation of the universal (fibred) product in the category of commutative associative algebras of finite type with unity over a field is given and proven. The field of coefficients is not supposed to be algebraically closed and can be of any characteristic. Formation of fibred product of commutative associative algebras is an algebraic counterpart of gluing algebraic schemes by means of some equivalence relation in algebraic geometry. If initial algebras are finite-dimensional vector spaces, the dimension of their product obeys a Grassmann-like formula. A finite-dimensional case means geometrically the strict version of adding two collections of points containing a common part.

The method involves description of algebras by generators and relations on input and returns similar description of the product algebra. It is "ready-to-eat" even for computer realization. The product algebra is well-defined: taking other descriptions of the same algebras leads to isomorphic product algebra. Also it is proven that the product algebra enjoys universal property, i.e. it is indeed a fibred product. The input data are a triple of algebras and a pair of homomorphisms $A_1 \xrightarrow{f_1} A_0 \xleftarrow{f_2} A_2$. Algebras and homomorphisms can be described in an arbitrary way. We prove that for computing the fibred product it is enough to restrict to the case when $f_i$, $i = 1, 2$ are surjective and describe how to reduce to the surjective case. Also the way of choosing generators and relations for input algebras is considered.

Paper is published in the author's wording.

Keywords: commutative algebras over a field, affine Grothendieck' schemes, universal product, amalgamated sum

Introduction

0.1. Motivation and General Problem

For a motivating example consider affine plane $k^2$ over a field $k$ and two non-proportional irreducible polynomials $g_1, g_2$ in two variables $x, y$ over the same field. Let these polynomials have zero sets $Z(g_1) \subset k^2 \supset Z(g_2)$ and a set of common zeros $Z(g_1, g_2) = Z(g_1) \cap Z(g_2)$. If $k$ is algebraically closed $Z(g_i)$ are irreducible curves for any $g_i, i = 1, 2$, and $Z(g_1, g_2)$ is a discrete collection of points. A union of curves $Z(g_1) \cup Z(g_2)$ is given by zeros of the product polynomial $g_1 g_2$, i.e. $Z(g_1) \cup Z(g_2) = Z(g_1, g_2)$ and provides a simple example of amalgamated sum $Z(g_1) \coprod_{Z(g_1, g_2)} Z(g_2)$ of algebraic schemes $Z(g_i), i = 1, 2$ (precise definition will be given below). Transferring to algebraic counterpart one has $k$-algebras $A_i = k[x, y]/(g_i), i = 1, 2$ corresponding to curves $Z(g_i), i = 1, 2$ respectively, and the $k$-algebra of intersection locus $A_0 = k[x, y]/(g_1, g_2)$. There are obvious $k$-algebra homomorphisms $f_i : A_i \rightarrow A_0$. Formation of the algebra $k[x, y]/(g_1, g_2)$ for the union of two components provides an example of universal (fibred) product of $k$-algebras $A_1 \times_{A_0} A_2$.

For our purposes it is enough to restrict by affine algebraic $k$-schemes of finite type, i.e. prime spectra (sets of prime ideals with natural topology and collection of local rings forming a structure sheaf on the spectrum) of commutative associative $k$-algebras of finite type with unity (for complete theory cf. [1, ch.2]). We focus on algebraic side and operate exclusively with underlying algebras.

We describe general quotient problem in the category of algebraic schemes over a field $k$. The problem includes following ingredients:

- a scheme $X$;
- a subscheme $R \subset X \times X$;
- morphisms $p_i : R \subset X \times X \rightarrow X$ defined as composites of the immersion with the projection on $i$th factor.

The subscheme $R \subset X \times X$ is said to be an equivalence relation; this means that it satisfies three requirements as follows:

1. $R$ is reflexive, i.e. $R \supset \text{diag}(X)$ where $\text{diag}(X)$ is an image of the diagonal immersion $\text{diag} : X \hookrightarrow X \times X$;

2. $R$ is symmetric, i.e. the immersion $R \subset X \times X$ is stable under the involution intertwining first and second factors of the product $X \times X$;

3. $R$ is transitive, i.e. $\text{pr}_{13}(R \times X \cap X \times R) \subset R$ where the intersection is taken in $X \times X \times X$. Here $\text{pr}_{13} : X \times X \times X \rightarrow X \times X$ is the projection to the product of the 1st and 3rd factors.

The question is [2, ch. 1, 4.3] to construct (if possible) the universal quotient $X/R$. This is an object fitting into the commutative diagram

\[
\begin{array}{ccc}
R & \xrightarrow{p_2} & X \\
\downarrow p_1 & & \downarrow \\
X & \longrightarrow & X/R
\end{array}
\]
such that for any other commutative square

\[
\begin{array}{ccc}
R & \xrightarrow{p_2} & X \\
\downarrow{p_1} & & \downarrow \\
X & \xrightarrow{\tau} & T
\end{array}
\]

there is a unique morphism \( \tau : X/R \to T \) (in the appropriate category) fitting into the commutative diagram

\[
\begin{array}{ccc}
R & \xrightarrow{p_2} & X \\
\downarrow{p_1} & & \downarrow \\
X & \xrightarrow{\tau} & X/R \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
T & & T
\end{array}
\]

The best result should be to know precisely when the universal quotient exist in some category (for example, in the category of algebraic schemes) and when it does not.

**0.2. Particular Cases**

1. The notion of algebraic space \([3]\) which appears when morphisms \( p_i, i = 1, 2 \) assumed to be étale. In this case the object \( X/R \) belongs to the category of algebraic spaces.

2. Open covering of a scheme \( Y \) when \( X = \bigsqcup U_\alpha \) is a disjoint union of open subschemes of \( Y \), \( R = \bigsqcup R_{\alpha\beta} \) and morphisms \( R_{\alpha\beta} \to U_\alpha \) and \( R_{\alpha\beta} \to U_\beta \) are local isomorphisms. In this case the object \( X/R \) is the scheme \( Y \) whose open cover was considered.

3. Let the scheme \( X \) is acted upon by an algebraic group \( G \) and \( R \) is a subscheme induced by \( G\)-equivalence \([4]\). In this case if \( X/G = X/R \) exists its universality means that it is a categorical quotient of the scheme \( X \) by \( G \).

**0.3. Case of Several Components**

Now let \( X \) be a disjoint union of schemes \( X = X_1 \bigsqcup X_2 \). Then

\[
X \times X = X_1 \times X_1 \bigsqcup X_1 \times X_2 \bigsqcup X_2 \times X_1 \bigsqcup X_2 \times X_2
\]

and the equivalence relation is broken into 4 disjoint components

\[
R = R_{11} \bigsqcup R_{12} \bigsqcup R_{21} \bigsqcup R_{22}.
\]

The problem reduces to the search of the universal completion of the diagram

\[
\begin{array}{ccc}
R_{ij} & \xrightarrow{p_j} & X_j \\
\downarrow{p_i} & & \downarrow \\
X_i & &
\end{array}
\]
This universal completion is called an **amalgam** (or an **amalgamated sum**) of schemes $X_i$ and $X_j$ with respect to $R_{ij}$ and is denoted as $X_i \coprod_{R_{ij}} X_j$. If for each pair $i, j = 1, 2$ the amalgam $X_i \coprod_{R_{ij}} X_j$ exists then $X/R = X \coprod R X = \coprod_{i,j} (X_i \coprod_{R_{ij}} X_j)$.

### 0.4. Schemes and algebras

We recall that affine Grothendieck’ scheme of finite type over a field $k$ is a prime spectrum $\text{Spec} \ A$ of associative commutative algebra $A$ of finite type with unity over $k$.

Recall that the $k$-algebra $A$ is said to be of finite type if it admits a surjective homomorphism of polynomial algebra in finite set of variables $k[x_1, \ldots, x_n] \to A$. In particular this means that the algebra $A$ under consideration can have any finite Krull dimension (if $A$ admits an epimorphism of polynomial algebra in $n$ variables then the Krull dimension of $A$ is not greater than $n$). In this case the algebra $A$ as $k$-vector space can be infinitely-dimensional.

Generally, fibred product and amalgam (or product and coproduct, or small limits) are dual categorical notions [5, 1.17,1.18] and are not obliged to exist in any category. The schemes under consideration are prime spectra of associative commutative algebras of finite type over $k$. Duality is done by functorial correspondence taking $k$-algebra to its prime spectrum. The fibred product of associative commutative $k$-algebras of finite type as taken by this functor to the amalgam of corresponding spectra. The functorial behavior of fibred product of algebras is analogous to one of fibred product of schemes.

Despite that existence of fibred product for associative commutative algebras is known, the method of explicit computation of it is not described in the literature. We fill this gap.

Let $A$ be a commutative associative algebra of finite type with unity; then it can be represented as a quotient algebra of $n$-generated polynomial algebra $\phi : k[x_1, \ldots, x_n] \to A$ where $n$ depends on the structure of $A$. The representing homomorphism $\phi$ corresponds to the immersion of the scheme $\text{Spec} \ A$ into $k$-affine space $\mathbb{A}^n = \text{Spec} \ k[x_1, \ldots, x_n]$. By means of this immersion we interpret the abstract $k$-scheme $Z$ as a closed subscheme $Z \subset \mathbb{A}^n$ of affine space. We call the isomorphism $A \cong k[x_1, \ldots, x_n]/\ker \phi$ (resp., the immersion $Z \subset \mathbb{A}^n$) the **affine representation** of the algebra $A$ (resp., scheme $Z$). This is the reason why any associative commutative algebra of finite type with unity is called an **affine algebra**. Then the $k$-algebra is affine if and only if it has affine representation. Any affine algebra has many different affine representations.

We prove the following result.

**Theorem 1.** *The universal (fibred) product of affine algebras of finite type over a field can be compute explicitly by means of generators and relations.*

The method to compute fibred products of affine algebras constitutes the main subject of this article and described below.

First we fix the terminology and describe the algorithm which constructs algebra to be a universal product of algebras by means of their appropriate affine representations. Then we confirm that choice of different appropriate affine representations leads to isomorphic algebras. Finally we prove the universality and hence confirm that the obtained algebra is indeed a fibred product.
I would like to thank the Delaunau Laboratory for the support during my work on this article and my Diploma student I. Chistousov for testing the finite-dimensional version of the method by thoroughly computing various examples.

1. Construction

1.1. Glossary

We work with polynomial rings of view $k[x_1, \ldots, x_n]$, its ideals and quotients.

The basis of the ideal $I$ is any system of generators of $I$ as $k[x_1, \ldots, x_n]$-module.

The basis is minimal if it does not span $I$ whenever any of elements is excluded.

The $k$-basis of polynomial algebra (which is not obliged to be with unity) is its basis if the algebra is considered as $k$-vector space.

The $k$-relation between elements of the algebra $A$ (which is not obliged to be with unity) is a nontrivial $k$-linear function (nontrivial $k$-linear combination) in these elements which equals 0 in $A$. As usually, linear combinations with finite number of nonzero coefficients are considered.

Fix the natural ordering of variables $x_1, \ldots, x_n$; then we can use shorthand notation $x^{\alpha}$ for the monomial $x_1^{\alpha_1} \ldots x_n^{\alpha_n}$. The symbol $\alpha$ denotes the row of degrees $\alpha_1, \ldots, \alpha_n$.

1.2. Algorithm

Reduction to surjective morphisms

We are given three algebras $A_0, A_1, A_2$ with morphisms $A_1 \xrightarrow{f_1} A_0 \xleftarrow{f_2} A_2$. Show that we can assume that both $f_i$, $i = 1, 2$ are surjective. Since the morphisms $f_i$ must include into commutative squares of the form

\[
\begin{array}{ccc}
A_0 & \xrightarrow{f_2} & A_2 \\
\downarrow{f_1} & & \downarrow{\chi_2} \\
A_1 & \xleftarrow{\chi_1} & A_T
\end{array}
\]

then for any such a commutative square the composite morphisms $f_1 \circ \chi_1$ and $f_2 \circ \chi_2$ have coincident images in $A_0$. By commutativity of the square $\text{im } f_1 \circ \chi_1 = \text{im } f_2 \circ \chi_2 \subset \text{im } f_i$, $i = 1, 2$. This means that $\text{im } f_1 \circ \chi_i \subset \text{im } f_1 \cap \text{im } f_2$ and the morphism $\chi_i$ factors through the subalgebra $f_i^{-1}(\text{im } f_1 \cap \text{im } f_2) \subset A_i$ for $i = 1, 2$. Then all algebras of interest $A_T$ complete the square

\[
\begin{array}{ccc}
\text{im } f_1 \cap \text{im } f_2 & \xleftarrow{f_1^{-1}(\text{im } f_1 \cap \text{im } f_2)} & \text{im } f_1 \cap \text{im } f_2 \\
\downarrow{f_1} & & \downarrow{f_2} \\
\text{im } f_1 \cap \text{im } f_2 & \xrightarrow{f_1^{-1}(\text{im } f_1 \cap \text{im } f_2)} & A_T
\end{array}
\]

to commute.

Denote $A_i' \xrightarrow{f_i'} A_0' \xleftarrow{f_i} A_2$ where $A_0' = \text{im } f_1 \cap \text{im } f_2$, $A_i' = f_i^{-1}(A_0')$ and $f_i' = f_i|_{A_i'}$, $i = 1, 2$. 
Let there be a fibred product \( A'_1 \times_{A'_0} A'_2 \) for the case \( A'_1 \xrightarrow{f'_1} A'_0 \xleftarrow{f'_2} A'_2 \). Confirm that \( A'_1 \times_{A'_0} A'_2 \) is also a universal product for the initial arbitrary data \( A_1 \xrightarrow{f_1} A_0 \xleftarrow{f_2} A_2 \). By the construction of algebras \( A'_i \), \( i = 0, 1, 2 \), and by the definition of the algebra \( A'_1 \times_{A'_0} A'_2 \) it includes into the commutative diagram

\[
\begin{array}{ccc}
A_0 & \xleftarrow{f_2} & A_2 \\
\uparrow & & \uparrow \\
A_0 & \xrightarrow{f_1} & A_1 \\
\uparrow & & \uparrow \\
A_1 & \xrightarrow{f'_1} & A'_1 \times_{A'_0} A'_2 \\
\uparrow & & \uparrow \\
A_1 & \xrightarrow{f'_2} & A'_2 \\
\uparrow & & \uparrow \\
A_2 & \xrightarrow{f_2} & A_2
\end{array}
\]

Let \( A_T \) fit into the commutative diagram (1). Then by the universality of \( A'_1 \times_{A'_0} A'_2 \) as a product there is a unique homomorphism \( \varphi : A_T \to A'_1 \times_{A'_0} A'_2 \) which fits in the commutative diagram

\[
\begin{array}{ccc}
A_0 & \xleftarrow{f_2} & A_2 \\
\uparrow & & \uparrow \\
A_0 & \xrightarrow{f_1} & A_1 \\
\uparrow & & \uparrow \\
A_1 & \xrightarrow{f'_1} & A'_1 \times_{A'_0} A'_2 \\
\uparrow & & \uparrow \\
A_1 & \xrightarrow{f'_2} & A'_2 \\
\uparrow & & \uparrow \\
A_T & \xrightarrow{\varphi} & A'_1 \times_{A'_0} A'_2 \\
\uparrow & & \uparrow \\
A_2 & \xrightarrow{f_2} & A_2
\end{array}
\]

This diagram provides universality of the algebra \( A'_1 \times_{A'_0} A'_2 \) as a product for initial data, i.e.

\[ A'_1 \times_{A'_0} A'_2 = A_1 \times_{A_0} A_2. \]

Now we can replace everywhere our initial arbitrary data by the more special case when morphisms \( f_i, i = 1, 2 \), are surjective.

**Easy case**

Assume that \( A_i \cong k[x_1, \ldots, x_n]/I_i, i = 0, 1, 2 \), so that \( A_0 = A_1 \otimes_{k[x_1, \ldots, x_n]} A_2 \). This assumption says that the subscheme \( \text{Spec } A_0 \cong Z_0 \subset \mathbb{A}^n \) is an intersection of subschemes \( Z_1 \subset \mathbb{A}^n \) and \( Z_2 \subset \mathbb{A}^n, Z_i \cong \text{Spec } A_i, i = 1, 2 \).

Choose minimal bases in ideals \( I_i, i = 1, 2 \). Consider set of those monomials in \( k[x_1, \ldots, x_n] \) which are taken to 0 in both \( A_1 \) and \( A_2 \) by homomorphisms \( f_1 \) and \( f_2 \) respectively. It is clear that if \( x^\alpha \) is such a monomial that for all \( \beta \in \mathbb{Z}_{\geq 0}^n \) the monomial \( x^{\alpha+\beta} \) is taken to 0 in both \( A_1, A_2 \). Then the set of monomials under consideration generates an ideal \( J \).
Quotient algebra \( k[x_1, \ldots, x_n]/J \) includes into the commutative square

\[
\begin{array}{ccc}
A_0 & \xrightarrow{f_2} & A_2 \\
\uparrow f_1 & & \uparrow \\
A_1 & \xleftarrow{k[x_1, \ldots, x_n]/J} &
\end{array}
\]

Consider \( k\)-basis elements in \( k[x_1, \ldots, x_n]/J \). Since \( A_i \) are not obliged to be finite-dimensional over \( k \), \( k[x_1, \ldots, x_n]/J \) can also have infinite \( k \)-basis. We form the list \( L \) of \( k \)-relations among \( k \)-basis elements of \( k[x_1, \ldots, x_n]/J \) as follows.

The \( k \)-relation \( \sum a_\alpha x^\alpha \) between elements of \( k[x_1, \ldots, x_n]/J \) (possibly monomial) is include into \( L \) if and only if it equals 0 in both of \( A_1, A_2 \). It is clear that the linear span \(< L \) is an ideal in \( k[x_1, \ldots, x_n]/J \).

Now set \( A = (k[x_1, \ldots, x_n]/J)/< L > = k[x_1, \ldots, x_n]/(J + < L >) \).

**Remark 1.** By Hilbert’s basis theorem, ideals \( J, < L > \), and \( J + < L > \) admit finite bases.

**Remark 2.** If \( A_1 \) and \( A_2 \) finite-dimensional then \( \dim A_1 \times A_0 A_2 = \dim A_1 + \dim A_2 - \dim A_0. \) This follows immediately from the algorithm described. If \( k \) is algebraically closed then length \( A_i = \dim A_i, i = 0, 1, 2 \), and then length \( A_1 \times A_0 A_2 = \text{length } A_1 + \text{length } A_2 - \text{length } A_0 \).

**Hard case**

How to build up affine representations of algebras \( A_0, A_1, A_2 \) to validate the Easy case, i.e. such that \( A_0 = A_1 \otimes k[x_1, \ldots, x_n] A_2 \)?

Start with principal ideals in \( A_0 \): only those which are maximal under inclusion are necessary. Take a generator of each such an ideal. Choose any maximal \( k \)-linearly independent subset in the set of generators chosen. Since \( A_0 \) is an algebra of finite type, this subset is obliged to be finite; let it consist of \( s \) elements \( g_1, \ldots, g_s \). Each element \( g_j \) corresponds to the variable \( x_j \) in \( k[x_1, \ldots, x_s] \). The construction done fixes a homomorphism of \( k \)-algebras \( h_0 : k[x_1, \ldots, x_s] \to A_0 \). Let \( K_0 := \ker h_0 \). Since \( k[x_1, \ldots, x_s] \) in Noetherian then \( K_0 \) is finitely generated ideal.

Let \( g_j' \) be one of preimages of the element \( g_j \in A_0 \) in \( A_1 \), \( g_j'' \) be one of preimages of the same element in \( A_2 \). We complete the set \( g_1', \ldots, g_s' \) to form the set of \( k \)-linearly independent generators of the algebra \( A_1 \), by adding elements \( g_{s+1}', \ldots, g_m' \in A_1 \). Similarly, the set \( g_1'', \ldots, g_s'' \) is completed to the set of \( k \)-linearly independent generators of the algebra \( A_2 \) by adding elements \( g_{m+1}'', \ldots, g_n'' \). We put the variables \( x_{s+1}, \ldots, x_{m} \) in the correspondence to the elements \( g_{s+1}', \ldots, g_m' \) and the variables \( x_{m+1}, \ldots, x_{n} \) to the elements \( g_{m+1}'', \ldots, g_n'' \).

This leads to homomorphisms \( h_i : k[x_1, \ldots, x_n] \to A_i, i = 0, 1, 2, n \geq s \) defined by
following correspondences

\[
\begin{align*}
    h_0(x_j) &= g_j, \quad j = 1, \ldots, s, \\
    h_0(x_j) &= 0, \quad j = s + 1, \ldots, n, \\
    h_1(x_j) &= g'_j, \quad j = 1, \ldots, m, \\
    h_1(x_j) &= 0, \quad j = m + 1, \ldots, n, \\
    h_2(x_j) &= g''_j, \quad j = 1, \ldots, s, m + 1, \ldots, n, \\
    h_2(x_j) &= 0, \quad j = s + 1, \ldots, m.
\end{align*}
\]

In particular, \( h_0 = f_1 \circ h_i \).

Affine representations of algebras \( A_0, A_1, A_2 \) and their homomorphisms \( f_1, f_2 \) lead to closed immersions of their spectra into affine space \( \mathbb{A}^n \) according to the following commutative diagram

\[
\begin{array}{ccc}
    \mathbb{A}^n & \xrightarrow{h_2^i} & \text{Spec } A_2 \\
    \downarrow{h_0^i} & & \downarrow{f_2^i} \\
    \text{Spec } A_1 & \xleftarrow{f_1^i} & \text{Spec } A_0
\end{array}
\]

By some modification of representing homomorphisms \( h_i, i = 0, 1, 2 \), we will easily achieve that in the appropriate affine space

\[
h_0^i(\text{Spec } A_0) = h_1^i(\text{Spec } A_1) \cap h_2^i(\text{Spec } A_2).
\]

For this purpose choose any system of generators \( \kappa_1, \ldots, \kappa_r \) of the ideal \( K_0 \) (as \( k[x_1, \ldots, x_n] \)-module). Add to the set of variables \( x_1, \ldots, x_n \) additional variables (whose number equals to the number \( r \) of generators if \( K_0 \) chosen) \( y_1, \ldots, y_r \), and consider in \( A_1 \)-algebra \( A_1[y_1, \ldots, y_r] \) an ideal \( K'_0 \) generated by all relations of view \( y_l - \kappa_i(g'_1, \ldots, g'_m), l = 1, \ldots, r \).

Then we have a commutative diagram

\[
\begin{array}{ccc}
    k[x_1, \ldots, x_n, y_1, \ldots, y_r] & \xrightarrow{k'_2} & A_2 \\
    \downarrow{k'_0} & & \downarrow{f_2} \\
    A_1[y_1, \ldots, y_r]/K'_0 & \xrightarrow{h'_1} & A_0
\end{array}
\]

There \( h'_i(x_j) = h_i(x_j) \) for \( j = 1, \ldots, n \) and for \( i = 0, 1, 2 \), but \( h'_i(y_j) = 0 \) for \( i = 0, 2 \) and \( j = 1, \ldots, r \).

**Lemma 1.** There is an isomorphism of \( k \)-algebras \( A_1[y_1, \ldots, y_r]/K'_0 \cong A_1 \).

**Proof.** Let \( K_1 = \ker h_1 \). Denote by \( J' \) the ideal in the ring \( k[x_1, \ldots, x_n, y_1, \ldots, y_r] \) which is generated by relations \( y_l - \kappa_i(x_1, \ldots, x_n), l = 1, \ldots, r \). Obviously, \( J' \subset \ker h'_1 \). The isomorphism of \( k[x_1, \ldots, x_n, y_1, \ldots, y_r] \)-modules \( A_1[y_1, \ldots, y_r]/K'_0 \cong A_1 \) follows from the
exact diagram of $k[x_1, \ldots, x_n, y_1, \ldots, y_r]$-modules

$$
\begin{array}{c}
\begin{array}{c}
0 \\
\downarrow \\
J' \sim \rightarrow (y_1, \ldots, y_r)
\end{array}
\end{array}

\begin{array}{c}
\begin{array}{c}
0 \\
\downarrow \\
\ker h'_1 \rightarrow k[x_1, \ldots, x_n, y_1, \ldots, y_r] \rightarrow A_1[y_1, \ldots, y_r]/K'_0 \rightarrow 0 \\
\downarrow \\
0
\end{array}
\end{array}

\begin{array}{c}
\begin{array}{c}
0 \\
\downarrow \\
K_1 \rightarrow k[x_1, \ldots, x_n] \rightarrow A_1 \rightarrow 0
\end{array}
\end{array}

\end{array}
$$

where the isomorphism $J' \cong (y_1, \ldots, y_r)$ is an isomorphism of free modules of equal ranks done by the correspondence $y_l - \kappa_l(x_1, \ldots, x_n) \mapsto y_l$, $l = 1, \ldots, r$. The $k$-algebra isomorphism $A_1[y_1, \ldots, y_r]/K'_0 \cong A_1$ follows from the fact that the quotient algebra $A_1[y_1, \ldots, y_r]/K'_0$ admits the same system of generators $g'_1, \ldots, g'_m$ as an algebra $A_1$, with same relations (equal to generators of the ideal $K_1$).

**Proposition 1.** The homomorphisms $h'_i$ lead to the expression

$$A_0 = A_1 \otimes_{k[x_1, \ldots, x_n, y_1, \ldots, y_r]} A_2.$$ 

**Proof.** To prove the proposition one needs to confirm that $A_0$ is universal as a coproduct. Let $Q$ be a $k$-algebra supplied with two homomorphisms $A_1 \xrightarrow{\varphi_1} Q \xleftarrow{\varphi_2} A_2$ such that the following diagram commutes:

$$
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
k[x_1, \ldots, x_n, y_1, \ldots, y_r] \xrightarrow{h'_i} A_2 \\
k[x_1, \ldots, x_n, y_1, \ldots, y_r] \xrightarrow{h'_i} A_1
\end{array}
\end{array}
\end{array}

\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
A_1 \xrightarrow{\varphi_1} Q \\
A_1 \xrightarrow{\varphi_2} A_2
\end{array}
\end{array}
\end{array}

\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
A_1 \xrightarrow{f_1} A_0 \\
A_1 \xrightarrow{f_2} A_0
\end{array}
\end{array}
\end{array}

\end{array}
$$

Commutativity of the ambient contour guarantees that $\varphi_1(A_1) = \varphi_2(A_2)$ and hence we can replace $Q$ by $\varphi_1(A_1) = \varphi_2(A_2)$. However we preserve the notation $Q$ but assume that homomorphisms $\varphi_i$ are surjective. By the construction of homomorphisms $h'_i$, the algebra $A_0$ is generated by the images of first $s$ variables $x_1, \ldots, x_s$.

Then by the commutativity of the ambient contour $\varphi_1 h'_i(x_j) = \varphi_2 h'_i(x_j)$ for $j = 1, \ldots, n$. In particular, by the construction of homomorphisms $h'_i$ (and of homomorphisms $h'_j$ built up by means of them), $\varphi_1 h'_i(x_j) = \varphi_2 h'_i(x_j) = 0$ for $j = s + 1, \ldots, n$. For $j = 1, \ldots, s$ we have $0 = \varphi_1 h'_1(y_l - \kappa_l(x_j)) = \varphi_2 h'_2(y_l - \kappa_l(x_j)) = -\varphi_2 h'_2 \kappa_l(x_j)$ for $l = 1, \ldots, r$ since $h'_2(y_j) = 0$. This implies that homomorphisms $\varphi_i$, $i = 1, 2$, factor through the algebra $A_0$.

The homomorphism $\varphi_0 : A_0 \rightarrow Q$ is uniquely defined on generators $h'_0(x_j)$ of $A_0$ by the correspondence $h_0(x_j) \mapsto \varphi_i h'_i(x_j)$, $i = 1, 2$, $j = 1, \ldots, s$. 

\[\square\]
Remark 3. Proposition 1 means that affine representations constructed are such that the intersection of images of schemes \( \text{Spec} \ A_1 \) and \( \text{Spec} \ A_2 \) under closed immersions into \( \text{Spec} \ k[x_1, \ldots, x_n, y_1, \ldots, y_r] = \mathbb{A}^{n+r} \) is the image of \( \text{Spec} \ A_0 \).

Remark 4. In further considerations we use the notation of the view

\[
A_1 \xleftarrow{h_1} k[x_1, \ldots, x_n] \xrightarrow{h_2} A_2
\]

assuming that homomorphisms \( h_i, \ i = 1, 2 \), are surjective and that they admit application of the Easy case, i.e. Proposition 1 holds for them.

2. Well-Definedness and Universality

2.1. Different affine representations chosen

Proposition 2. Different affine representations of algebras \( A_0, A_1, A_2 \) lead to isomorphic product algebras \( A \).

Proof. Let we have two pairs of different affine representations defined by pairs of homomorphisms

\[
A_1 \xleftarrow{h_1} k[x_1, \ldots, x_n] \xrightarrow{h_2} A_2 \text{ and } A_1 \xleftarrow{h'_1} k[x'_1, \ldots, x'_m] \xrightarrow{h'_2} A_2
\]

such that \( A_0 = A_1 \otimes_k k[x'_1, \ldots, x'_m] A_2 = A_1 \otimes_k k[x_1, \ldots, x_n] A_2 \). They correspond to two pairs of closed immersions of prime spectra

\[
\text{Spec} \ A_1 \xhookrightarrow{h_1^*} \mathbb{A}^n \xleftarrow{h_2^*} \text{Spec} \ A_2 \text{ and } \text{Spec} \ A_1 \xhookrightarrow{h'_1^*} \mathbb{A}^m \xleftarrow{h'_2^*} \text{Spec} \ A_2
\]

such that \( h_1^*(\text{Spec} \ A_1) \cap h_2^*(\text{Spec} \ A_2) = h_0^*(\text{Spec} \ A_0) \) and \( h'_1^*(\text{Spec} \ A_1) \cap h'_2^*(\text{Spec} \ A_2) = h'^*_0(\text{Spec} \ A_0) \). This leads to closed immersions \( \overline{h}_i^* : \text{Spec} \ A_i \hookrightarrow \mathbb{A}^n \times \mathbb{A}^m = \mathbb{A}^{n+m} \) as composites with the diagonal immersion diag:

\[
\overline{h}_i^* : \text{Spec} \ A_i \xhookrightarrow{\text{diag}} \text{Spec} \ A_i \times \text{Spec} \ A_i \xrightarrow{(h_i^*, h_i'^*)} \mathbb{A}^n \times \mathbb{A}^m.
\]

Now confirm that in this case also \( \overline{h}_1^*(\text{Spec} \ A_1) \cap \overline{h}_2^*(\text{Spec} \ A_2) = \overline{h}_0^*(\text{Spec} \ A_0) \).

Homomorphisms \( \overline{h}_i \) are defined as composites

\[
k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{(h_i, h'_i)} A_i \otimes_k A_i \xrightarrow{\delta_i} A_i,
\]

\[
g_1 \otimes g_2 \mapsto h_i(g_1) \otimes h'_i(g_2) \mapsto h_i(g_1) \cdot h'_i(g_2).
\]

Let \( Q \) be an algebra together with two homomorphisms \( \varphi_1 : A_i \to Q \) such that \( \varphi_1 \circ \overline{h}_1 = \varphi_2 \circ \overline{h}_2 \). To confirm that \( A_0 = A_1 \otimes_k k[x'_1, \ldots, x'_m] \otimes_k k[x_1, \ldots, x_n] A_2 \) it is necessary to construct a unique homomorphism \( \varphi_0 : A_0 \to A_T \) such that \( \varphi_i = \varphi_0 \circ f_i \). Consider commutative diagrams

\[
\begin{array}{ccc}
A_i \otimes_k A_i & \xrightarrow{(f_i, f_i)} & A_0 \otimes_k A_0 \\
\delta_i \downarrow & & \downarrow \delta_0 \\
A_i & \xrightarrow{f_i} & A_0
\end{array}
\]

\[
\begin{array}{ccc}
A_0 & \xrightarrow{\varphi_0} & Q \\
\varphi_i \downarrow & & \downarrow \varphi_i \\
A_i & \xrightarrow{f_i} & A_0
\end{array}
\]

\[
\begin{array}{ccc}
A_i & \xrightarrow{\delta_i} & A_i \otimes_k A_i \\
\varphi_i \downarrow & & \downarrow \varphi_0 \\
A_i & \xrightarrow{f_i} & A_0
\end{array}
\]
for $i = 1, 2$. Let for any reducible tensor $x \otimes x' \in A_i \otimes_k A_i$
\[
(f_i, f_i)(x \otimes x') = \pi \otimes \pi' \in A_0 \otimes_k A_0; \\
f_i(x \cdot x') = \pi \otimes \pi' \in A_0; \\
\delta_i(\pi \otimes \pi') = \pi \cdot \pi' \in A_0;
\]
the homomorphism $\varphi_i'$ is uniquely defined using homomorphisms
\[
(\varphi_i, \varphi_i) : A_i \otimes_k A_i \to Q : x \otimes x' \mapsto \varphi_i(x) \cdot \varphi_i(x')
\]
as
\[
\varphi_i'(\pi \otimes \pi') = \varphi_i(x) \cdot \varphi_i(x') \in Q
\]
then $\varphi_0 : A_0 \to Q$ is also uniquely defined as $\varphi_0(\overline{y}) = \varphi_i(y)$ for $\overline{y} = f_i(y)$, $y \in A_i$.

Now it rests to form product algebras for three different affine representations
\[
k[x_1, \ldots, x_n] \xrightarrow{\lambda} k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{\rho} k[x'_1, \ldots, x'_m]
\]
Horizontal homomorphisms are defined by correspondences $\lambda : x'_i \mapsto 0$, $l = 1, \ldots, m$ and $\rho : x_j \mapsto 0$, $j = 1, \ldots, n$ respectively.

Denoting by $\overline{A}$ the product algebra for $\overline{k}_i : k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \to A_i$, $i = 0, 1, 2$, we come to the commutative diagram
\[
\begin{array}{c}
k[x_1, \ldots, x_n] \xrightarrow{\lambda} k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{\rho} k[x'_1, \ldots, x'_m] \\
A \xrightarrow{p_A} \overline{A} \xrightarrow{p'_A} A'
\end{array}
\]
associated to closed immersions
\[
\begin{array}{c}
\mathbb{A}^n \hookrightarrow \mathbb{A}^n \times \mathbb{A}^m \xhookrightarrow{\rho} \mathbb{A}^m, \\
(x_1, \ldots, x_n) \longmapsto (x_1, \ldots, x_n, 0, \ldots, 0), \\
(0, \ldots, 0, x'_1, \ldots, x'_m) \longmapsto (x'_1, \ldots, x'_m).
\end{array}
\]
Vertical homomorphisms in (2) define affine representations for product algebras built up according to the Easy case. Lower horizontal morphisms are surjective by commutativity of the diagram (2).

To prove isomorphicity of lower homomorphisms in (2) consider sections of homomorphisms $k[x_1, \ldots, x_n] \xleftarrow{\lambda} k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{\rho} k[x_1, \ldots, x_m]$, i.e. homomorphisms $k[x_1, \ldots, x_n] \xrightarrow{s_1} k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{s_2} k[x_1, \ldots, x_m]$ defined by following rules $s_1 : f \mapsto f \otimes 1$, $s_2 : g \mapsto 1 \otimes g$. A nonzero element from $A$ has nonzero preimage in $k[x_1, \ldots, x_n]$ which has nonzero image in $k[x_1, \ldots, x_n] \otimes k[x'_1, \ldots, x'_m]$. This image is
taken to nonzero element of at least one of algebras $A_1$, $A_2$ and hence has nonzero image in $\overline{A}$. This leads to a homomorphism of $k$-algebras $s_A : A \to \overline{A}$. It is a section of the homomorphism $p_A$ by its construction.

Now remark that $s_A$ is surjective. Indeed, one can choose a system of $k$-generators (which is not obliged to be a basis) in $\overline{A}$ which are images of reducible tensors $f \otimes g$ from $k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m]$, $f \in k[x_1, \ldots, x_n]$, $g \in k[x'_1, \ldots, x'_m]$. This expression is defined up to the action of $k^* = k \setminus \{0\}$. A polynomial $f$ has nonzero image at least in one of algebras $A_1, A_2$. Hence it is taken to nonzero element in $A$. Since $p_A \circ s_A = \text{id}_A$ then both $s_A$ and $p_A$ are isomorphisms.

Isomorphism of $p'_A$ is proven analogously. \qed

### 2.2. Universality

**Proposition 3.** The construction of product algebra $A$ is indeed universal, i.e. $A$ is true fibred product.

**Proof.** Let $A_T$ be an affine $k$-algebra together with two homomorphisms $\chi_i : A_T \to A_i$, $i = 1, 2$ such that $\chi_1 \circ f_1 = \chi_2 \circ f_2$. We construct a homomorphism $\varphi$ to complete the diagram

\[
\begin{array}{ccc}
A_T & \xrightarrow{\varphi} & A \\
\chi_1 & \downarrow & \chi_2 \\
A_1 & \longrightarrow & A_2
\end{array}
\]

Choose appropriate affine representations of algebras $A_T, A, A_i$, $i = 1, 2$. Perform the manipulations as described in the Easy case. Namely, let $J$ be an ideal in $k[x_1, \ldots, x_n]$ generated by all monomials taken to 0 in $A_T$, $A$ and $A_i$, $i = 1, 2$.

Quotient algebra $k[x_1, \ldots, x_n]/J$ includes in the commutative diagram

\[
\begin{array}{ccc}
A_0 & \xrightarrow{f_1} & A_1 \\
\chi_1 & \downarrow & \chi_1 \\
A_T & \longrightarrow & A_T \\
\chi_2 & \downarrow & \chi_2 \\
A_2 & \longrightarrow & A_2
\end{array}
\]

Choose an arbitrary element $\alpha \in A_T$; it is taken to $\chi_1(\alpha) \in A_1$ and to $\chi_2(\alpha) \in A_2$ so that $f_1\chi_1(\alpha) = f_2\chi_2(\alpha)$. Any $\gamma$ of preimages of $\alpha$ in $k[x_1, \ldots, x_n]/J$ is also taken to $f_1\chi_1(\alpha) = f_2\chi_2(\alpha) \in A_0$ and to some element $\overline{\alpha} \in A$. We claim that $\overline{\alpha}$ does not depend on the choice of $\gamma$.

Choose another $\gamma' \in k[x_1, \ldots, x_n]/J$ taken to $\alpha$, then $\gamma - \gamma'$ maps to zero in $A_T$ and hence it is mapped to zero in both $A_i$, $i = 1, 2$. Then by the construction of $A$ (cf. Easy case) $\gamma - \gamma'$ is taken to zero in $A$. This shows that there is a homomorphism $\varphi : A_T \to A$ such that $\chi_i = \varphi \circ \overline{f}_i$, $i = 1, 2$, as required.

It rests to confirm ourselves that the homomorphism $\varphi : A_T \to A$ does not depend on the choice of affine representations of algebras $A_T, A_i$, $i = 0, 1, 2$. For this sake assume
that there are two different collections of affine representations include into commutative diagrams

\[
\begin{align*}
&k[x_1, \ldots, x_n] \quad k[x'_1, \ldots, x'_m] \\
&\downarrow h_1 \quad \downarrow h'_1 \\
&A_1 \quad A_1 \\
&f_1 \quad f_1
\end{align*}
\]

Then consider the algebra \( k[x_1, \ldots, x_n] \otimes k k[x'_1, \ldots, x'_m] \) and its homomorphisms on quotient algebras \( k[x_1, \ldots, x_n] \xrightarrow{\lambda} k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m] \xrightarrow{\rho} k[x'_1, \ldots, x'_m] \) which are defined by their kernels \( \ker \lambda = (x'_1, \ldots, x'_m) \), \( \ker \rho = (x_1, \ldots, x_n) \) and correspond to immersions of subspaces \( \mathbb{A}^n \xrightarrow{\lambda} \mathbb{A}^n \times \mathbb{A}^m \xrightarrow{\rho} \mathbb{A}^m \) as linear subvarieties. Representations (3) define induced affine representations for algebras \( A_T, A_i \), \( i = 0, 1, 2 \), according to the following rule: \( \overline{h}_T(x_j \otimes x'_i) = h_T(x_j) \cdot h'_T(x'_i) \), \( \overline{h}_i(x_j \otimes x'_i) = h_i(x_j) \cdot h'_i(x'_i) \), \( i = 0, 1, 2 \), \( i = 1, \ldots, n \), \( l = 1, \ldots, m \). This rule corresponds to the composites of immersions of prime spectra

\[
\begin{align*}
\overline{h}_T & : \text{Spec } A_T \xrightarrow{\text{diag}} \text{Spec } A_T \times \text{Spec } A_T \xrightarrow{\text{diag}} \mathbb{A}^n \times \mathbb{A}^m, \\
\overline{h}_i & : \text{Spec } A_i \xrightarrow{\text{diag}} \text{Spec } A_i \times \text{Spec } A_i \xrightarrow{\text{diag}} \mathbb{A}^n \times \mathbb{A}^m.
\end{align*}
\]

Let \( J \) be the ideal generated by all monomials in \( k[x_1, \ldots, x_n] \) taken to 0 in \( A_T \) and in \( A_i \), \( i = 0, 1, 2 \), \( J' \) be the similar ideal in \( k[x'_1, \ldots, x'_m] \), and \( \overline{J} \) the similar ideal in \( k[x_1, \ldots, x_n] \otimes k [x'_1, \ldots, x'_m] \). Quotient algebras by these ideals include into the following commutative diagram

\[
\begin{align*}
&k[x_1, \ldots, x_n] \quad k[x'_1, \ldots, x'_m] \\
&\downarrow \lambda \quad \downarrow \rho \\
&k[x_1, \ldots, x_n]/J \quad k[x'_1, \ldots, x'_m]/J' \\
&\downarrow \\
&k[x_1, \ldots, x_n]/J \leftarrow k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m]/J \rightarrow k[x'_1, \ldots, x'_m]/J'
\end{align*}
\]

Now we perform the construction of homomorphisms \( \varphi, \varphi' \) and \( \overline{\varphi} \) using quotient algebras \( k[x_1, \ldots, x_n]/J, k[x'_1, \ldots, x'_m]/J' \) and \( k[x_1, \ldots, x_n] \otimes k[x'_1, \ldots, x'_m]/J \) respectively, as described in the beginning of this subsection. This yields in two commutative diagrams

\[
\begin{align*}
&k[x_1, \ldots, x_n]/J \quad k[x_1, \ldots, x_n] \otimes_k k[x'_1, \ldots, x'_m]/J' \\
&\downarrow \varphi \quad \downarrow \rho \\
&A_T \quad A_T
\end{align*}
\]
The list $A$ of monomials vanishing in both algebras cannot be involved to construct their product since $A_1 \otimes_{k[x,y]} A_2 = k[x,y]/(x^2-y) \neq A_0$. Then it is necessary to form a new affine representation which fits for constructing a product, using Hard case.

The algebra $A_0 = k[x]/(x^2)$ contains unique maximal principal ideal. Its generating element $x$ corresponds to first variable $x_1$ and gives rise to the affine representation $k[x_1] \rightarrow A_0$, $x_1 \mapsto x$. Further, manipulations according to the Hard case lead to the polynomial algebra $k[x_1, x_2, x_3, y]$ and representations for algebras

$$A_1 = k[x_1, x_2, x_3, y]/(x_1^2 - x_2, x_3, x_1^2 - y), \quad A_2 = k[x_1, x_2, x_3, y]/(x_2^2 - x_3, x_2, y).$$

These algebras represent geometrically two parabolas with common tangent line in two 2-dimensional planes in 4-dimensional affine space. Planes meet along this tangent line. In this case

$$A_1 \otimes_{k[x_1, x_2, x_3, y]} A_2 = k[x_1, x_2, x_3, y]/(x_1^2 - x_2, x_3, x_1^2 - y, x_1^2 - x_3, x_2, y) = k[x_1, x_2, x_3, y]/(x_1^2 - x_2, x_3) = A_0.$$ 

This means that our two parabolas intersect along the subscheme defined by the algebra $A_0$. This validates application of Easy case to affine representations we’ve constructed. The list $J$ of monomials vanishing in both algebras $A_i$, $i = 1, 2$, is empty. The ideal $< L >$ has a form $< L > = (x_1^2 - x_2, x_3, x_2 - y, x_2x_3)$, and $A_1 \times_{A_0} A_2 = k[x_1, x_2, x_3, y]/< L > = k[x_1, x_2, x_3]/(x_2 - x_3, x_2 - y, x_2x_3) = k[x_1, x_2, x_3]/(x_1^2 - x_2 - x_3, x_2x_3)$. From the geometrical point of view this is union of two parabolas having a common tangent line at the origin. Parabolas lie in different 2-planes which meet along parabolas’ common tangent line.

Аннотация. В работе дан и обоснован метод прямого вычисления универсального (расслоенного) произведения в категории коммутативных ассоциативных алгебр конечного типа с единицей над полем. Поле коэффициентов не предполагается алгебраически замкнутым и может иметь любую характеристику. Формирование расслоенного произведения коммутативных ассоциативных алгебр составляет алгебраическую сторону процедуры склеивания алгебраических схем по некоторому отношению эквивалентности в алгебраической геометрии. Если исходные алгебры являются конечномерными векторными пространствами, то размерность их расслоенного произведения подчиняется формуле, аналогичной формуле размерности суммы подпространств. Геометрически конечномерный случай поставляет строгую версию объединения двух наборов точек, имеющих общую часть. Метод использует задание алгебр образующими и определяющими соотношениями на входе и выдает аналогичное представление произведения на выходе. Он пригоден для компьютерной реализации. Произведение алгебр определено корректно: выбор иных представлений тех же алгебр приводит к изоморфной алгебре-произведению. Также показано, что алгебра-произведение обладает свойством универсальности, т.е. является настоящим расслоенным произведением. Входные данные – это тройка алгебр и пара гомоморфизмов \( f_1 : A_1 \rightarrow A_0 \) и \( f_2 : A_0 \leftarrow A_2 \). Алгебры и гомоморфизмы могут быть заданы произвольным образом. Показано, что для вычисления расслоенного произведения достаточно ограничиться случаем, когда гомоморфизмы \( f_i, i = 1, 2 \) сюръективны, и описан способ редукции к сюръективному случаю. Также рассмотрено правило выбора образующих и соотношений для исходных алгебр.

Статья публикуется в авторской редакции.
